

# Ch 3: DNS Vulnerabilities

Updated 6-19-23

# Causes of Vulnerabilities

- Configuration errors
- Architecture mistakes
- Vulnerable software implementations
- Protocol weaknesses
- Failure to use the security extensions in the protocol

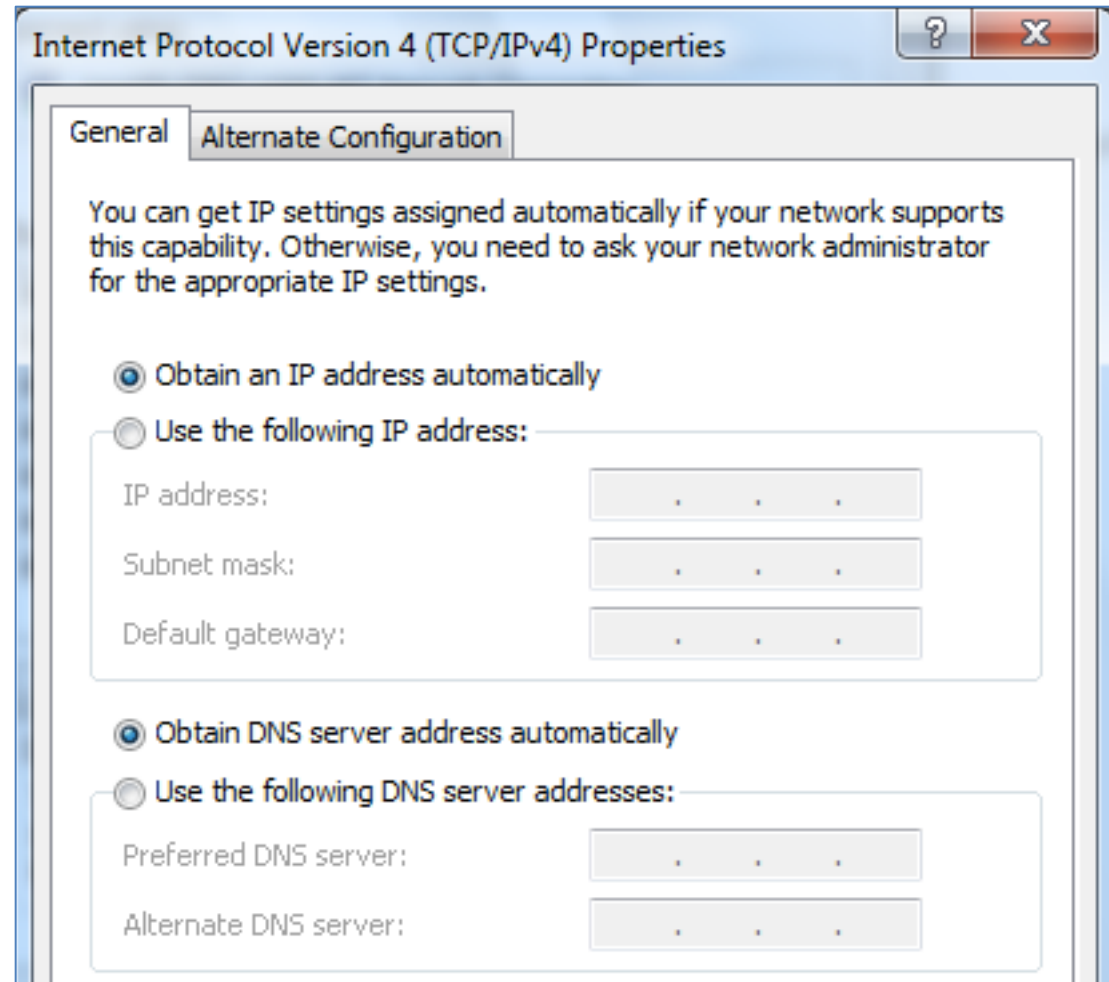

# DNS Architecture Mistakes

# Single Point of Failure

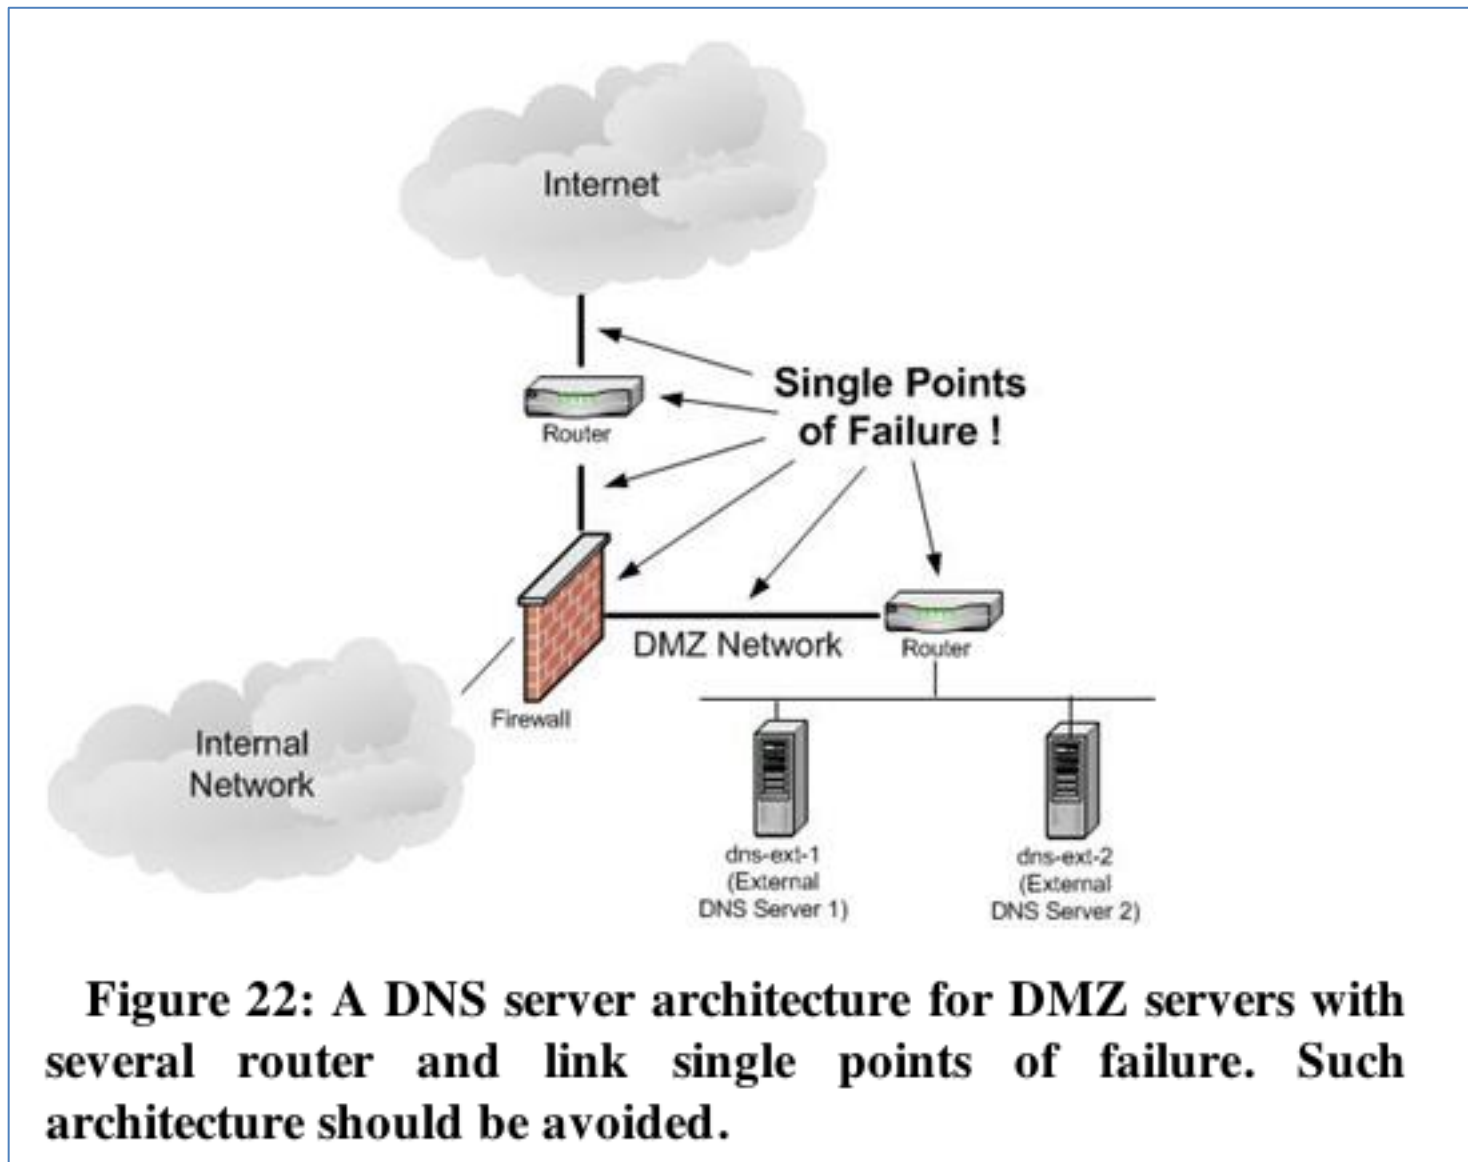

- The SOA could be a single server at a single site
  - If the server crashes, clients would be unable to resolve any of the domains in the zone
  - Also Internet connection outage, power failure, fire, storm, etc.
- If a single server is the recursive resolver for clients in an intranet
  - They'll all lose DNS service if it goes down

# Two Servers

- Many hosting providers do not allow delegation of DNS service to a single DNS server name
- End devices are typically provisioned with two DNS server addresses

# Router or Link

**Figure 22: A DNS server architecture for DMZ servers with several router and link single points of failure. Such architecture should be avoided.**

# Data Center or Single Site

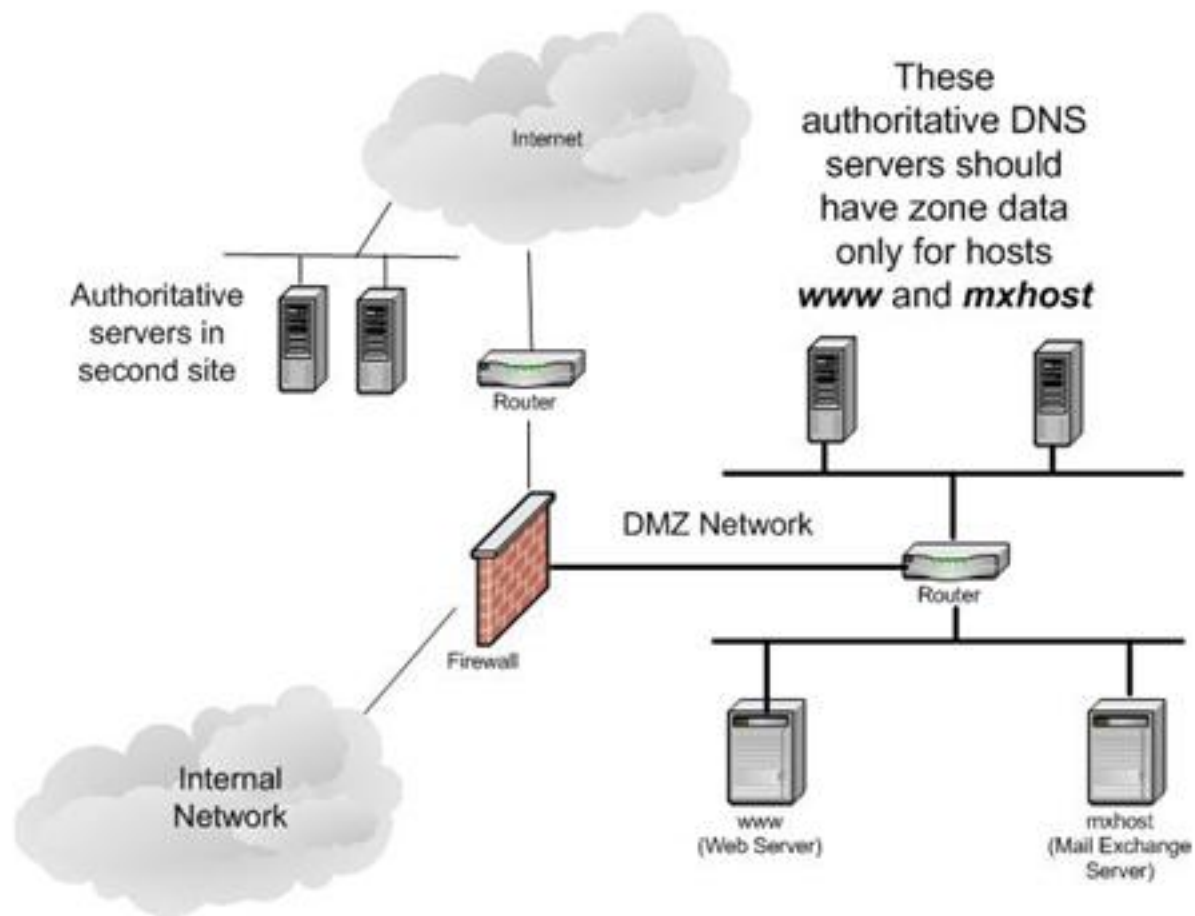

- If all DNS servers are at a single site or data center, a regional event could take them all down
  - Earthquake
  - Power failure
- The more critical the DNS service is, the more distributed servers should be
  - Geographically and topologically
  - Like the 13 root servers

# Common Configuration Errors

# Exposure of Internal Information

- Only public Web-facing servers should be in the external DNS zone files
- Your DNS server is a target of attack and may be compromised

**Figure 23: Authoritative servers should have zone data only for Internet-facing servers of the domain.**

# Leakage of Internal Queries to the Internet

- Some Windows DHCP clients leak dynamic DNS updates to the Internet
  - Link Ch 3a

**Table 1: Logical steps of sending DNS updates (not all packet exchanges are shown)**

	From	To	Content
1	DHCP Clt	Broadcast	DHCP Request
2	DHCP Srv	DHCP Clt	DHCP ACK: 192.168.0.2
3	DHCP Clt	LDNS	Query: SOA? hostname.ex.com
4	LDNS	DHCP Clt	Response: SOA dns.ex.com
5	DHCP Clt	dns.ex.com	Update:A hostname.ex.com
6	DHCP Clt	LDNS	Query:SOA? 2.0.168.192.in-addr.arpa
7	LDNS	DHCP Clt	Response:SOA prisoner.iana.org
8	DHCP Clt	prisoner	Update:PTR 2.0.168.192.in-addr.arpa

# Win Server 2008

- Stupid queries to see if private addresses are registered in public DNS
- Expose internal information

Source	Destination	Protocol	Length	Source Port	Info
192.168.119.191	192.175.48.6	DNS	84	65105	Standard query 0x416c SOA 119.168.192.in-addr.arpa

192.175.48.1	192.168.119.191	DNS	80	53	Dynamic update response 0x67a9 Refused
192.175.48.1	192.168.119.191	DNS	80	53	Dynamic update response 0x67a9 Refused

# Fixing the Problem

- To prevent this, configure local DNS servers not to refer internal machines to external name servers
  - And block DNS requests directly to the Internet

# Unnecessary Recursiveness

- Not all name servers need to be recursive
  - Authoritative servers don't need to
  - Recursion is complex and burdens servers
  - Added function means more potential vulnerabilities
- Recursion may be on by default
  - Thousands of open recursive resolvers on the Internet

# Failure to Restrict Access

- Recursive DNS servers should only accept queries from your own clients
  - Block outside addresses with access control lists

# Testing for Open Resolvers

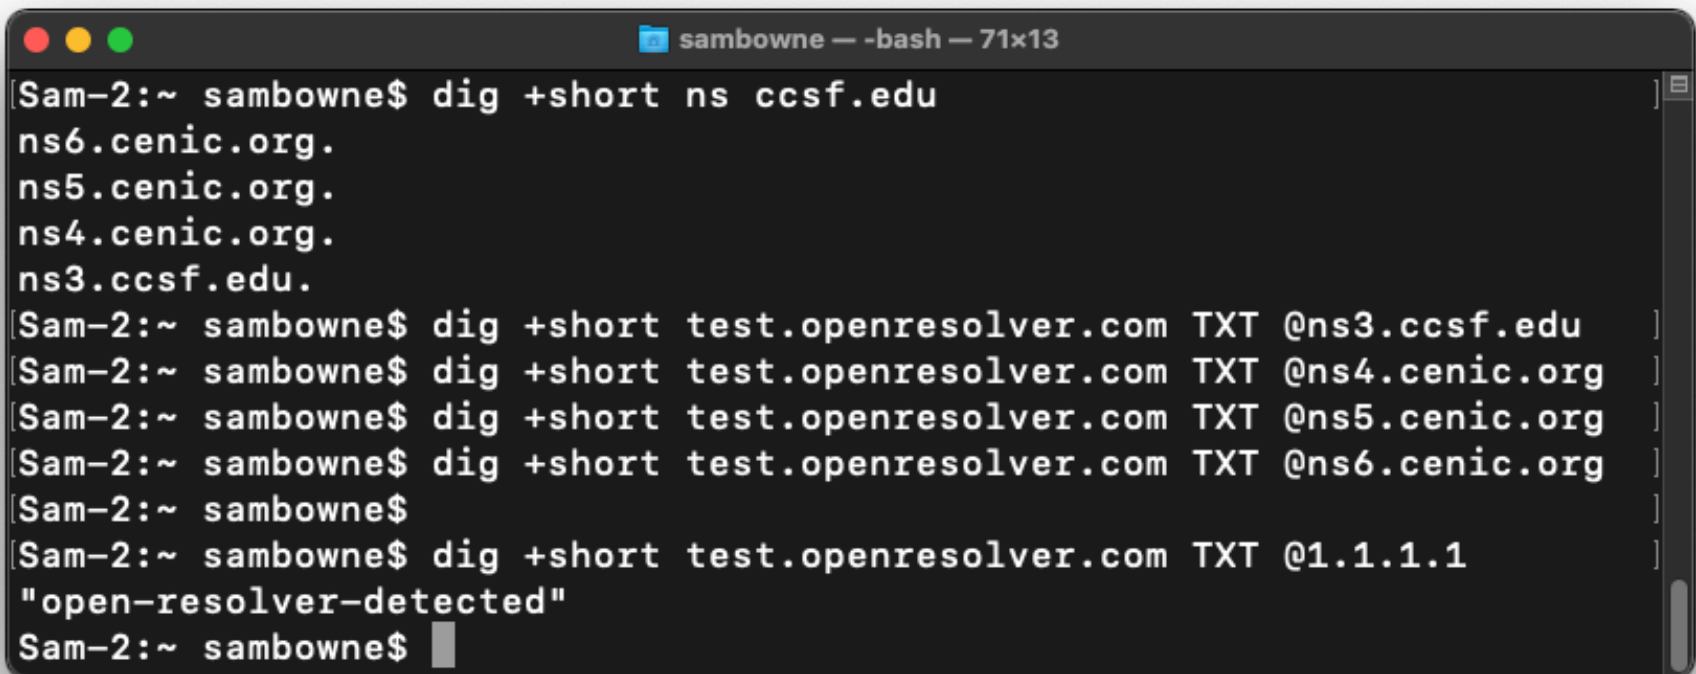

- `dig +short test.openresolver.com TXT @1.2.3.4`

# Testing CCSF's DNS Servers in 2023

- All are closed

```
sambowne — -bash — 71x13
[Sam-2:~ sambowne$ dig +short ns ccsf.edu

```

# Unprotected Zone Transfers

- Data transfers from a master to a slave authoritative server
  - Update the zone files on the slave
- Can be requested by any other host
- Reveals information about all hosts in the zone
  - Information disclosure vulnerability

# North Korea

## North Korea .kp TLD Zone Data

---

On Sept 19, 2016 at approximately 10:00PM (PDT), one of North Korea's top level nameservers was accidentally configured to allow global DNS zone transfers. This allows anyone who performs an `AXFR` (zone transfer) request to the country's `ns2.kptc.kp` nameserver to get a copy of the nation's top level DNS data. This was detected by the [TLDR Project](#) - an effort to attempt zone transfers against all top level domain (TLD) nameservers every three hours and keep a running Github repo with the resulting data. This data gives us a better picture of North Korea's domains and top level DNS.

## Search Results

There are **87** CVE Records that match your search.

Name	Description
<a href="#">CVE-2022-38178</a>	By spoofing the target resolver with responses that have a malformed EdDSA signature, an attacker can trigger a small memory leak. It is possible to gradually erode available memory to the point where named crashes for lack of resources.
<a href="#">CVE-2022-38177</a>	By spoofing the target resolver with responses that have a malformed ECDSA signature, an attacker can trigger a small memory leak. It is possible to gradually erode available memory to the point where named crashes for lack of resources.
<a href="#">CVE-2022-3080</a>	By sending specific queries to the resolver, an attacker can cause named to crash.
<a href="#">CVE-2022-2906</a>	An attacker can leverage this flaw to gradually erode available memory to the point where named crashes for lack of resources. Upon restart the attacker would have to begin again, but nevertheless there is the potential to deny service.
<a href="#">CVE-2022-2881</a>	The underlying bug might cause read past end of the buffer and either read memory it should not read, or crash the process.
<a href="#">CVE-2022-2795</a>	By flooding the target resolver with queries exploiting this flaw an attacker can significantly impair the resolver's performance, effectively denying legitimate clients access to the DNS resolution service.

# Severe 2008 Bind Vulnerability

## **CVE-2008-0122**

VU#203611

**Summary:** Off-by-one error in the `inet_network` function in `libbind` in ISC BIND 9.4.2 and earlier, as used in `libc` in FreeBSD 6.2 through 7.0-PRERELEASE, allows context-dependent attackers to cause a denial of service (crash) and possibly execute arbitrary code via crafted input that triggers memory corruption.

**Published:** 01/16/2008

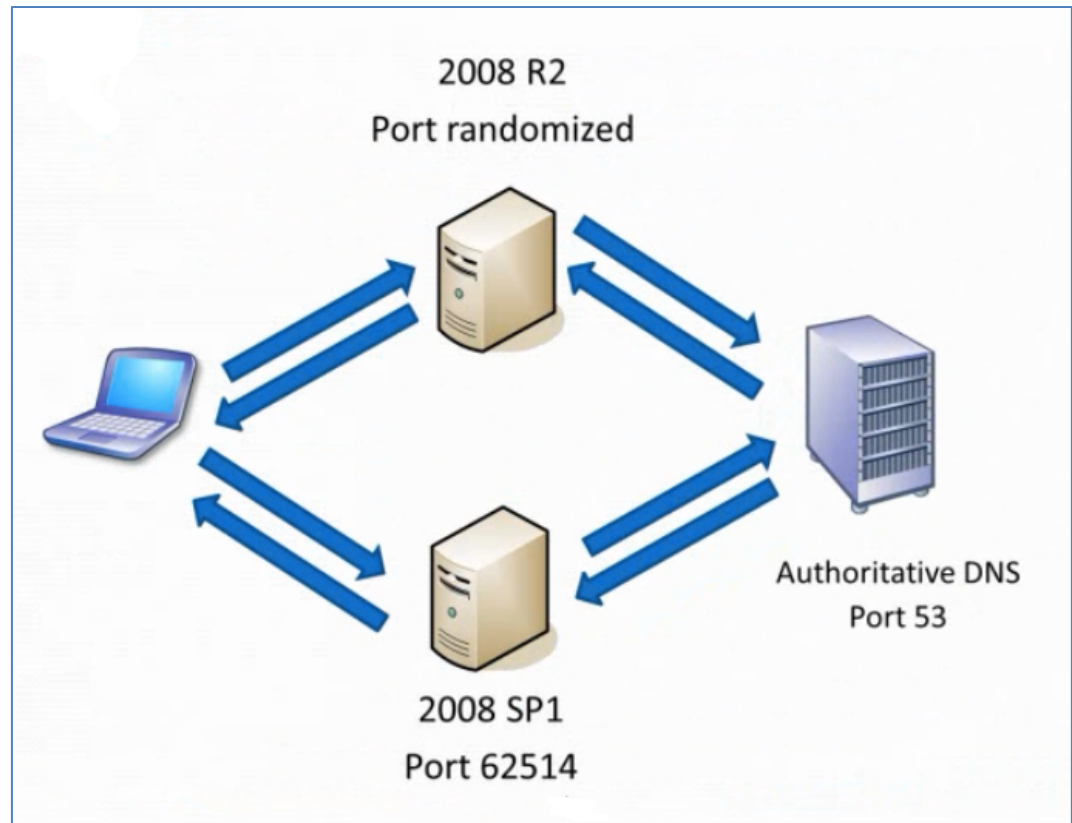

**CVSS Severity:** 10.0 (HIGH)

- Attack used an IP address like
  - 1.2.3.4.xxxxxxxx-exploit-code-here-xxxx
- Another list of DNS vulns at link Ch 3d

# Source Port Randomization

- Good video
- Link Ch 3e

# Randomness of Transaction ID

- Each DNS query and response has a TXID field
  - 16 bits long (65,536 possible values)
  - Should be random
- Bind 8 & 9 used predictable transaction IDs
  - So only ten guesses were needed to spoof the reply

# Randomness of Transaction ID

# Tricking a Target into Using Your DNS Server

- Run a domain *evil.com* with a SOA you control *ns1.evil.com*
  - Send the target an email with a link to *server.evil.com* and hope someone clicks it
  - Send email from *joe@evil.com* to target email address
    - The server will automatically perform a reverse lookup to detect spam

# Tricking a Target into Making Multiple DNS Queries

- CNAME Chaining
  - *www.evil.com* is a CNAME for *www1.evil.com*
  - *www1.evil.com* is a CNAME for *www2.evil.com*
  - *www2.evil.com* is a CNAME for *www3.evil.com*
  - etc.

# Tricking a Target into Making Multiple DNS Queries

- NS Referral Chaining and NS Chains
  - *a.a.a.a.evil.com* has SOA *ns.evil.com*
  - *ns.evil.com* delegates to *ns.a.evil.com*
  - *ns.a.evil.com* delegates to *ns.a.a.evil.com*
  - etc.

# Protocol Design Weaknesses

# Weak Authentication

- DNS uses these elements to match a request and a response
  - Transaction ID (16 bits)
  - Question
  - Source and destination IP
  - Source and destination ports
    - But request destination port is known (53)
- Client accepts the first response that meets these criteria, and caches the result

# DNS Cache Poisoning

- A false response that tricks the client puts a false entry into its cache

# DNS Cache Poisoning

Attacker  
1.2.3.4

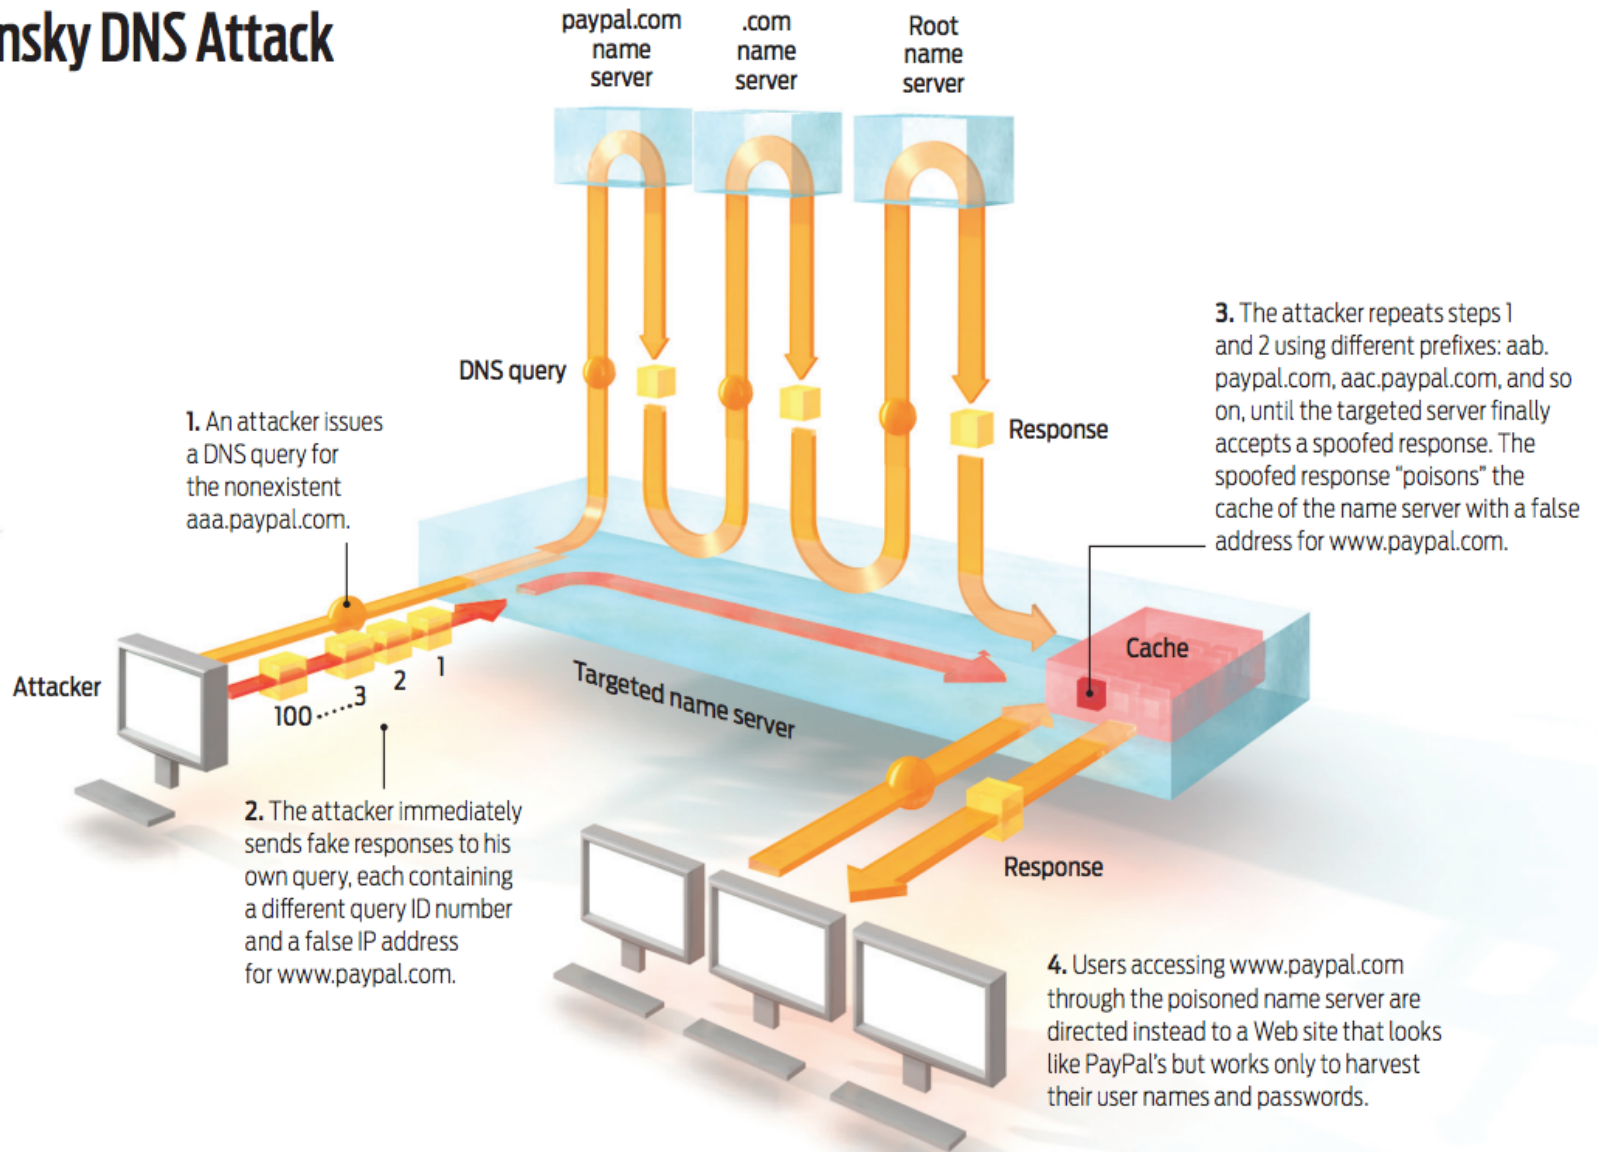

Target

DNS  
Resolver

# Kaminsky DNS Attack

- Link Ch 3f

Imagine that a resolver asks for the IP address of `doesnotexist.example.com`. An attacker sends back a response that looks like this:

```
$ dig doesnotexist.example.com
;; ANSWER SECTION:
doesnotexist.example.com. 120 IN A 10.10.10.10

;; AUTHORITY SECTION:
example.com. 86400 IN NS www.example.com .

;; ADDITIONAL SECTION:
www.example.com . 604800 IN A 10.10.10.20
```

An attacker is trying to trick the resolver into believing that **`www.example.com`** now lives at `10.10.10.20`, and to remember that for 604800 seconds (7 days). This

- Link Ch 3g

# Consequences of the Kaminsky Attack

- Attack can be placed in a Web page
  - Many img tags
  - `<img src=aaaa.paypal.com>`
  - `<img src=aaab.paypal.com>`
  - `<img src=aaac.paypal.com>`
  - `<img src=aaad.paypal.com>`
  - etc.
- If one Comcast customer views that page, all other Comcast customers will be sent to the fake paypal.com
- Poisoning can take as few as 10 seconds

# Man-in-the-Middle Attacks

- Attacker in the middle has enough info to perfectly forge responses
  - Unless DNSSEC is used

# DNS as a DoS Amplifier

- Small requests lead to large responses
- UDP allows spoofing the source IP address

**Kahoot!**
